1. Create a two-column table; the first column stores the number of languages, and the second column stores the type of language (compiled, interpreted, or both).

6	Compiled
6	Interpreted
8	Both

2. Discuss the real-world example where Python performance is superior to compiled languages such as C++. To answer this question, you need to do some research.
    a. When comparing Python to C++, developer speed versus execution speed is what sets them apart. According to Sigmaschool on Youtube, “In the tech industry, a company’s most expensive asset is human engineering time, not server compute power. Python allows developers to write, test, and deploy software in a fraction of the time it takes in C++.
3. Take a screenshot that shows that Python3 is installed successfully on your PC. The screenshot should show the installed Python version.

4. Take a screenshot that shows that the GitHub repository is all set up for this course.
